Technical Note
A dynamic model for the interaction of the cable bridge and train system

M.M. Jalili1*, A.H. Orafa2
Received: December 2013, Revised: April 2014, Accepted: December 2014

Abstract

The vibration of cable-stayed bridges subjected to the passage of high-speed trains is studied in this article. The moving train includes a number of wagons, each of which is modeled as a four-axle system possessing 48 degrees of freedom. The car model is nonlinear and three-dimensional and includes nonlinear springs and dampers of primary and secondary suspensions, dry friction between different parts and also clearances and mechanical stops. Two parallel rails of the track are modeled as Euler-Bernoulli beams on elastic points as rail pads. The rail irregularities are assumed to be stationary random and ergodic processes in space, with Gaussian amplitude probability densities and zero mean values. The bridge deck is modeled as a plate supported by some cables. The current model is validated using several numerical models reported in the literature of the earlier researcher.

Keywords: Rail vehicle dynamics, Euler-Bernoulli beam, Levy method, Random rail irregularities.

1. Introduction

To meet the economic, social and recreational needs of the community for safe and efficient transportation systems, more and more cable bridges have been built throughout the world. Cable-stayed bridges were often constructed for crossing wide rivers and deep valleys or existing urban structures because of their economic and aesthetic advantages. The investigation of the cable bridge vibration under moving train using different models has been widely reported in the literature. For most of the previous studies the cable-stayed bridge has been modeled as a planar system. Au et al. [1] used 2-D model to study bridge vibration due to random rail irregularities. They studied effects of number of random samples, damping, class of railway, track quality and initial motion of train vehicles on bridge vibration. Using a planar model for vehicle/bridge, the vibration reduction of cable bridges excited by high-speed trains is studied by Yau and Yang [2]. 2-D models cannot simulate lateral vibration of the bridge. In addition wagon derailment and hunting vibration cannot be investigated by these models.

For the 3-D models, the finite element method has been used as the main tool for bridge simulation. For instance, using FEM, the vibration of coupled train and cable-stayed bridge systems in cross winds has been investigated by Xu et al. [3]. Also, the dynamic stability of trains moving over bridges shaken by earthquakes has been studied by Yang and Wu [4]. Using this model the maximum allowable speed for the train to run safely has been obtained under the specified ground acceleration.

In this article, an analytical solution is presented for simulation of the coupled system. A 3-D model of the cable-stayed bridge, rails and passenger wagon is developed. Equations of motion of this model are derived. Using the proposed model, the effects of wagon parameters, lateral position of the rails and the rail irregularities on vehicle/track dynamics are studied.

2. System Model

2.1. The train model

A 3-D model of a 2-axle passenger wagon with 48 DOF is developed here. All parts of primary and secondary suspension systems with their nonlinear characteristics, friction between moving elements, the effect of wheel flange contact with the rail, wheel rail nonlinear contact forces, kinematics constraint of bogie center plate, and the contact forces between side pads and bogie frame are considered in this model. Schematic of wagon model is shown in Figure 1. Basic dynamic parameters of wagon are presented in Table 1.

Fig. 1 Schematic view of the wagon model: (1) wagon body, (2) bolster, (3) secondary suspension system, (4) bogie, (5) primary suspension system, (6) wheelset, and (7) rail
Considering the nature of this problem, use of 3-dimensional wheelset model is essential. Determination of the correct contact point between wheel and rail and the exact value of the contact force between the two members are the major issues in 3-D modeling of the wheelset. To determine normal contact force between the wheel and rail, a flexible wheel–rail contact model based on semi-Hertzian methods and the virtual penetration theory has been used [5]. Also in order to determine the tangential forces, the FASTSIM algorithm has been used.

The connection link between wagons is considered to be hooks and draft gears [6]. The buffers at each side of the cars have also been included in the model to account for the absorption of the excess energy in inter-wagon force transmissions (Fig. 2). The degrees of freedom for the wagon components are listed in Table 2.

Table 3 \( A_v \), coefficient related to line grade[1]

2.2. The bridge model

Figure 3 shows the bridge model adopted in the present study. The bridge deck is modeled as a plate supported by some cables. Also the bridge towers are modeled as a beam in lateral and a bar in vertical direction. Rails are modeled as Euler-Bernoulli beams on elastic points as rail pads (Fig. 4).
2.3. Irregularities model

Rail irregularities generally have a random distribution, and are considered as one of the major sources of wagon vibration and wheelset derailment. The major causes of these irregularities are: incompatible substrate conditions, weather conditions, rail age and excessive train commutation on rails [7].

The random rail irregularities are assumed to be stationary random and ergodic processes in space, with Gaussian amplitude probability densities and zero mean values. They are characterized by their respective one-sided power spectral density functions $G_{N}(\omega)$ where $\omega$ is the route frequency. Fryba [8] has summarized various commonly used power spectral density functions. In the present study, the power spectral density functions based on the results of measurements on US railway tracks is adopted, with the empirical formula for evaluation of irregularities as:

$$G_{N}(\omega) = A_{s} \omega^2 \left( \omega^2 + \omega^2_{s} \right)$$  \hspace{1cm} (1)

Where $\omega_{s} = 0.0233 \text{ m}^{-1}$ and $\omega_{s} = 0.131 \text{ m}^{-1}$ and the parameter $A_{s}$ is a coefficient related to line grade, as shown in Table [1].

A sample function of rail irregularities $r^{d}(x)$ generated numerically using the following series:

$$r^{d}(x) = \sum_{k=1}^{N} a_{k} \cos(\omega_{k} x + \phi_{k})$$ \hspace{1cm} (2)

Where $a_{k}$ is the amplitude of the cosine wave, $\omega_{k}$ is a frequency within the interval $[\omega_{u}, \omega_{a}]$ in which the power spectral density function is defined, $\phi_{k}$ is a random phase angle with uniform probability distribution in the interval $[0, 2\pi]$. $x$ is the global coordinate measured from the start of the rail section and $N$ is the total number of terms used to generate the rail irregularities function. The parameters $a_{k}$ and $\omega_{k}$ are computed using equations Eq.(3) and Eq.(4):

$$a_{k} = 2 \sqrt{G_{N}(\omega_{u})} \Delta \omega$$ \hspace{1cm} (3)

$$\omega_{k} = \omega_{u} + (k - \frac{1}{2}) \Delta \omega$$ \hspace{1cm} (4)

$$\Delta \omega = \left( \omega_{a} - \omega_{u} \right) / N$$ \hspace{1cm} (5)

In which $\omega_{u}$ and $\omega_{a}$ are the upper and lower limits of the frequency, and $N$ is a sufficiently large integer. Using equations Eq. (1-5), random rail irregularities in each line grade can be generated.

3. Equations of Motion

3.1. Deck equation of motion

Describing the bridge deck as a plate, the vertical vibration of the bridge deck is given by:

$$\frac{\partial^{4} w_{s}(x,y,t)}{\partial x^{4}} + 2 \frac{\partial^{4} w_{s}(x,y,t)}{\partial x^{2} \partial y^{2}} + \frac{\partial^{4} w_{s}(x,y,t)}{\partial y^{4}} + \frac{\rho h_{t}}{D_{s}} \frac{\partial^{2} w_{s}(x,y,t)}{\partial t^{2}} = - \frac{1}{D_{s}} \left( F_{u}^{*} + \sum_{k=1}^{K} F_{u_{k}} \right)$$ \hspace{1cm} (6)

Where

$$F_{u_{k}} = \sum_{j=1}^{N_{x}} \left[ K_{f} (w_{s}(x_{j},y_{s},t) - w_{s}(x_{j},t)) + C_{f} (\dot{w}_{s}(x_{j},y_{s},t) - \dot{w}_{s}(x_{j},t)) \times \delta(x-x_{j}) \delta(y-y_{s}) \right]$$ \hspace{1cm} (7)

$$F_{u}^{*} = \sum_{c=1}^{N_{x}} \frac{E_{s} A_{s}}{L_{c}} \left( C_{1} \delta(y) + C_{3} \delta(y-b) \right) \delta(x-x_{c}) \sin(\alpha_{c}) + \sum_{c=2N_{x}+1}^{3N_{x}} \frac{E_{s} A_{s}}{L_{c}} \left( C_{1} \delta(y) + C_{3} \delta(y-b) \right) \delta(x-x_{c}) \sin(\alpha_{c}) + \sum_{c=2N_{x}+1}^{3N_{x}} \frac{E_{s} A_{s}}{L_{c}} \left( C_{2} \delta(y) + C_{4} \delta(y-b) \right) \delta(x-x_{c}) \sin(\alpha_{c}) + \sum_{c=3N_{x}+1}^{4N_{x}} \frac{E_{s} A_{s}}{L_{c}} \left( C_{2} \delta(y) + C_{4} \delta(y-b) \right) \delta(x-x_{c}) \sin(\alpha_{c})$$ \hspace{1cm} (8)
in which
\[
  C_{1k} = -w_t(x,0,t)\sin(\alpha_t) + w_{tt}(H)\cos(\alpha_t) + w_{tt}(H)\sin(\alpha_t)
\]
\[
  C_{2k} = -w_t(x,0,t)\sin(\alpha_t) - w_{tt}(H)\cos(\alpha_t) + w_{tt}(H)\sin(\alpha_t)
\]
\[
  C_{3k} = -w_t(x,b,t)\sin(\alpha_t) + w_{tt}(H)\cos(\alpha_t) + w_{tt}(H)\sin(\alpha_t)
\]
\[
  C_{4k} = -w_t(x,b,t)\sin(\alpha_t) - w_{tt}(H)\cos(\alpha_t) + w_{tt}(H)\sin(\alpha_t)
\]

And
\[
  D_s = \frac{E_s h_s^3}{12(1-\nu_s^2)}
\]

Using Levy method, the solution of homogenous form of Eq. (6) can be expressed as [9]:
\[
  w_i(x,y,t) = X_m(x)Y_m(y)T_m(t) = \sin\left(\frac{m\pi x}{l}\right)Y_m(y)T_m(t)
\]

Substituting Eq. (11) into homogenous form of Eq. (6) yields:
\[
  \left[(\frac{m\pi}{a})^4 Y'''' + 2\left(\frac{m\pi}{a}\right)^2 Y''' + Y'' + \frac{p h_y}{D_s} Y'\right]\sin\left(\frac{m\pi x}{a}\right) = 0
\]

Using Separation of variables, vibration frequencies can be found as:
\[
  \frac{p h_y}{D_s}\left[-\frac{m\pi}{a} \right]^4 + 2\left(\frac{m\pi}{a}\right)^2 \frac{Y_m'''}{Y_m''} + \frac{Y_m''}{Y_m'} = \frac{m\pi}{a} = \omega_{mn}^2
\]

and finally a differential equation can be derived as follows:
\[
  Y_m'' - 2\left(\frac{m\pi}{a}\right)^2 Y_m'' - \left(\frac{p h_y}{D_s}\right) \omega_{mn}^2 - \left(\frac{m\pi}{a}\right)^4 Y_m = 0
\]

The bending moments and the shearing forces for the two free edges at \(y=0\) and \(y=b\) are equal to zero. So the boundary conditions are:
\[
  Y_m'' \bigg|_{y=0,b} = 0, \quad Y_m''' \bigg|_{y=0,b} = 0
\]

\[
  Y_m'' \bigg|_{y=0,b} = 0, \quad Y_m''' \bigg|_{y=0,b} = 0
\]

\(Y_m\) and \(\omega_{mn}\) can be achieved by Substituting the solution of Eq. (14) into Eq. (15) and Eq. (16) and solving the obtained homogeneous system.

Solution of Eq. (6) Can be written in the form of Eq. (11). With same \(X_m\) and \(Y_m\) from homogenous solution. Substituting Eq. (11) into Eq. (6) yields:
\[
  \sum_{m=1}^{N_x} \sum_{n=1}^{N_y} X_m^{(4)} Y_m T_m + 2\sum_{m=1}^{N_x} \sum_{n=1}^{N_y} X_m^{(2)} Y_m^{(2)} T_m + \sum_{m=1}^{N_x} \sum_{n=1}^{N_y} X_m Y_m^{(4)} T_m + \frac{p h_y}{D_s} \sum_{m=1}^{N_x} \sum_{n=1}^{N_y} X_m Y_m T_m = -\frac{1}{D_s} (F_{z,y} + \sum_{k=1}^{K} F_{z,k})
\]

Multiplying Eq. (17) By \(X_k(x)Y_\alpha(y)\) and then applying integral in the plate area yields the second-order ordinary differential equations of the plate vertical vibration in terms of the generalized coordinate \(T_{mn}(t)\) as follows:
\[ T_{mn} + \frac{D}{\rho h} \left( \frac{B_1 B_2 + 2 B_4 B_5 + B_6 h}{B_2} \right) T_{mn} = \]
\[ \frac{1}{\rho h B_2} \sum_{c=1}^{N_c} \frac{E A_c}{L_c} \left( C_{11} X_m(x_c) Y_{mn}(0) + C_{33} X_m(x_c) Y_{mn}(b) \right) \sin(\alpha_c) \]
\[ + \frac{2\pi c}{\rho h B_2} \sum_{c=N_c+1}^{N_c} \frac{E A_c}{L_c} \left( C_{21} X_m(x_c) Y(0) + C_{41} X_m(x_c) Y(b) \right) \sin(\alpha_c) \]
\[ + \frac{2\pi c}{\rho h B_2} \sum_{c=2N_c+1}^{N_c} \frac{E A_c}{L_c} \left( C_{12} X_m(x_c) Y(0) + C_{34} X_m(x_c) Y(b) \right) \sin(\alpha_c) \]
\[ + \frac{4\pi c}{\rho h B_2} \sum_{c=3N_c+1}^{N_c} \frac{E A_c}{L_c} \left( C_{22} X_m(x_c) Y(0) + C_{44} X_m(x_c) Y(b) \right) \sin(\alpha_c) \]
\[ - \frac{1}{\rho h B_2} \sum_{c=1}^{N_c} \frac{E A_c}{L_c} \left[ K_f (w_m(x_c, y, t) - w_m(x_c, y, t)) + C_f (\dot{w}_m(x_c, y, t) - \dot{w}_m(x_c, y, t)) \right] X_m(x_c) Y_{mn}(y) \]

Where
\[
\begin{cases}
B_1 = \int_0^b X_m^2 dx \\
B_2 = \int_0^b Y_m^2 dy \\
B_3 = \int_0^b X_m^{(4)} X_m dx \\
B_4 = \int_0^b Y_m^{(4)} Y_m dy
\end{cases}
\]

3.2. Tower equation of motion

Describing each tower as an Euler-Bernoulli beam, the lateral vibration of tower is given by:
\[
E I_{\alpha} \frac{\partial^4 w^x_{\alpha}(x, t)}{\partial x^4} + \rho A \frac{\partial^2 w^x_{\alpha}(x, t)}{\partial t^2} = (F_{\alpha} - \bar{F}_{\alpha})
\]

in which
\[
\begin{align*}
F_{\alpha} &= \sum_{c=1}^{N_c} \frac{E A_c}{L_c} C_{21} \delta(x - H) \cos(\alpha_c) \\
F_{\bar{\alpha}} &= \sum_{c=1}^{N_c} \frac{E A_c}{L_c} C_{33} \delta(x - H) \cos(\alpha_c) \\
F_{\beta l} &= \sum_{c=1}^{N_c} \frac{E A_c}{L_c} C_{41} \delta(x - H) \cos(\alpha_c) \\
F_{\bar{\beta l}} &= \sum_{c=1}^{N_c} \frac{E A_c}{L_c} C_{34} \delta(x - H) \cos(\alpha_c)
\end{align*}
\]

In order to solve the homogenous form of differential equation in Eq.(20); the solution can be expressed as:
\[
w^x_{\beta l} = X^x_{\beta l}(x) \times T^x_{\beta l}(t)
\]

Where
\[
\begin{align*}
X^x_{\beta l} &= A_1 \cos(\beta_l x) + A_2 \sin(\beta_l x) + A_3 \cosh(\beta_l x) + A_4 \sin(\beta_l x)
\end{align*}
\]

And; the boundary conditions are:
\[
\begin{align*}
w^x_{\beta l}(0, t) &= 0 \\
\frac{\partial^2 w^x_{\beta l}(0, t)}{\partial x^2} &= 0 \\
\frac{\partial^2 w^x_{\beta l}(H, t)}{\partial x^2} &= 0 \\
\frac{\partial^2 w^x_{\beta l}(H, t)}{\partial x^3} &= 0
\end{align*}
\]
\[ T_{ci}^{*} + \frac{EI}{\rho A} \dot{T}_{ci}^{*} = \frac{1}{\rho A B} \times \]

\[
\left[ \sum_{c=1}^{2N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) \right] + \sum_{c=3N_c+1}^{4N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) \\
+ \sum_{c=1}^{2N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) + \sum_{c=3N_c+1}^{4N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) \\
- \left( \sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) + \sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) \right) \\
\sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) + \sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) \right] \\
\sum_{c=1}^{3N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) + \sum_{c=1}^{3N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \cos(\alpha_c) \right]
\]

Where

\[ B_0 = \int_0^H X_{ik}^2 \, dx \]  \hspace{2cm} (28)

For analysis of vertical vibrations of tower, each tower is considered as a bar.

\[ E_A \frac{\partial^2 w_{ij}^2}{\partial t^2} - \rho A \frac{\partial^2 w_{ij}^2}{\partial t^2} = (F_{\text{str}} + F_{\text{d}}) \]  \hspace{2cm} (29)

Where

\[ F_{\text{str}} = \sum_{c=1}^{2N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \]

\[ F_{\text{d}} = \sum_{c=1}^{4N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \]

\[ F_{\text{b}} = \sum_{c=1}^{2N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \]

\[ F_{\text{d}} = \sum_{c=1}^{4N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \]

And

\[ T_{ci}^{*} + \frac{EI}{\rho A} \dot{T}_{ci}^{*} = \frac{-1}{\rho A H^2} \times \]

\[
\left[ \sum_{c=1}^{2N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \right] + \sum_{c=3N_c+1}^{4N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \\
+ \sum_{c=1}^{2N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) + \sum_{c=3N_c+1}^{4N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \\
- \left( \sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) + \sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \right) \\
\sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) + \sum_{c=1}^{N_c} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \right] \\
\sum_{c=1}^{3N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) + \sum_{c=1}^{3N_c+1} \frac{E_A}{L_c} C_{ci} \delta(x-H) \sin(\alpha_c) \right]
\]

The boundary conditions are:

\[ w_{ij}^* (0, t) = 0, \quad \frac{\partial w_{ij}^* (H, t)}{\partial x} = 0 \]  \hspace{2cm} (32)

The solution can be expressed as:

\[ w_{ij}^* = \sum_{l=1}^{L} X_{ij}^l(x) T_{ij}^* (t) = \sum_{l=1}^{L} \sin(\frac{(2l-1)\pi}{2H} x) T_{ij}^* (t) \]  \hspace{2cm} (33)

Substituting Eq.(33) into Eq.(29) yields:

\[ [-E_A \frac{(2l-1)\pi}{2H} x T_{ij}^* - \rho A T_{ij}^*] \sin(\frac{(2l-1)\pi}{2H}) = F_{\text{str}} + F_{\text{d}}^* \]  \hspace{2cm} (34)

Using same approach:
3.3. Rail equation of motion

Describing each rail as an Euler-Bernoulli beam, the vertical vibration of rail is given by:

\[ F_{w_k} = \sum_{j=1}^{N_r} \left[ K_f \left( w_j(x_j, y_k, t) - w_k(x_j, t) \right) + C_f \left( \dot{w}_j(x_j, y_k, t) - \dot{w}_k(x_j, t) \right) \right] \delta (x - x_j) \]

\[ F_{w_{rk}} = \sum_{w=1}^{4} F_{w}^w \delta (x - (v_w t + L_w)) \]

The boundary conditions are:

\[
\begin{align*}
& w_i(0, t) = 0 \quad \frac{\partial^2 w_i(0, t)}{\partial x^2} = 0 \\
& w_i(a, t) = 0 \quad \frac{\partial^2 w_i(a, t)}{\partial x^2} = 0
\end{align*}
\]

(39)

The solution can be determined as:

\[
T_{k_i} + \frac{E I}{\rho A B_i} T_{k_i} = -\frac{1}{\rho A B_i} \sum_{w=1}^{4} F_{w} X_{k_i} (x - (v_w t + L_w)) + \frac{1}{\rho A B_i} \sum_{j=1}^{N_r} \left[ K_f \left( w_j(x_j, y_k, t) - w_k(x_j, t) \right) + C_f \left( \dot{w}_j(x_j, y_k, t) - \dot{w}_k(x_j, t) \right) \right] X_{k_i}(x_j)
\]

(42)

where

\[
B_i = \int_0^a X_{k_i}^4 X_{k_i} d\phi = \left( \frac{l}{a} \right)^4 \frac{a}{2}, \quad B_0 = \int_0^a X_{k_i} X_{k_i} d\phi = \frac{a}{2}
\]

(43)

3.4. Equation of motion of the vehicle

Two coordinate systems are attached to the centers of masses of the model parts. One fixed to the part and rotates with it (denoted by the index “r”), and the other one is fixed at the initial position of the object (denoted by the index “o”). Also as shown in Figure 2 a coordinate system is fixed to the bridge deck as reference.

Using Figure 5, the relationship between components of an arbitrary vector in rotating and initial coordinate systems can be given as:

\[
R_i^o = R_{\phi,\psi} R_{\beta,\gamma} R_{\varphi,\sigma}
\]

\[
= \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \varphi & -\sin \varphi \\ 0 & \sin \varphi & \cos \varphi \end{bmatrix} \begin{bmatrix} \cos \beta & 0 & \sin \beta \\ 0 & 1 & 0 \\ -\sin \beta & 0 & \cos \beta \end{bmatrix} \begin{bmatrix} \cos \psi & -\sin \psi & 0 \\ \sin \psi & \cos \psi & 0 \\ 0 & 0 & 1 \end{bmatrix}
\]

(44)
Also angular velocity can be obtained as:

\[
\omega = \dot{\psi} \hat{k} + \dot{\beta} \hat{j} + \phi \hat{i} \\
= \dot{\psi} \hat{k} + \dot{\beta}(\hat{j} \cos \psi + \hat{i} \sin \psi) + \phi(\hat{i} \cos \beta + \hat{k} \sin \beta) \\
= \dot{\psi} \hat{k} + \dot{\beta}(\hat{j} \cos \psi + \hat{i} \sin \psi) \\
+ \phi(\hat{i} \cos \psi \cos \beta - \hat{j} \sin \psi \cos \beta + \hat{k} \sin \beta) \\
= (\beta \sin \psi + \phi \cos \psi \cos \beta) \hat{i} + (\dot{\beta} \cos \psi - \phi \sin \psi \cos \beta) \hat{j} \\
+ (\psi \dot{\phi} \sin \beta) \hat{k}
\]

And angular accelerations are:

\[
\begin{align*}
\dot{\omega}^x &= \ddot{\beta} \sin \psi + \dot{\beta} \psi \cos \psi + \dot{\phi} \cos \psi \cos \beta - \phi \dot{\beta} \sin \beta \cos \psi \\
&\quad - \phi \psi \cos \beta \sin \psi \\
\dot{\omega}^y &= \ddot{\beta} \cos \psi - \dot{\beta} \psi \sin \psi - \dot{\phi} \sin \psi \cos \beta + \phi \dot{\beta} \cos \beta \sin \psi \\
&\quad - \phi \psi \cos \beta \cos \psi \\
\dot{\omega}^z &= \ddot{\psi} \dot{\psi} + \ddot{\phi} \sin \beta + \dot{\phi} \dot{\beta} \cos \beta
\end{align*}
\]

For each wagon part, the equations of motion can be written as [10]:

\[
\sum F^o = m \ddot{w}^o \\
\sum M' = \frac{dH'}{dt} = I' \dot{\omega}^x + \omega^x \times I' \omega^x \rightarrow I' \dot{\omega}^x = \sum M' - \omega^x \times I' \omega^x
\]

The complete system equations are obtained by combining the equations of motions of deck, towers, rails and the wagon parts. Considering the initial conditions (wagon velocity and position), the equations of motion are solved numerically using Runge-Kutta method. In this method the system equations are converted into state variables. Both displacements and velocities at time \( t + \Delta t \) are treated as unknown and then can be obtained from the information of the time \( t \) [11].

### 4. Results and Discussions

In order to study the effects of various parameters on the behavior of a vehicle–bridge interaction, Evripos bridge in Greece is chosen as a case study. The main parameters of the rails and the bridge used in the simulation are listed in Tables 4-5 [12].

Figure 6 shows the maximum amplitude of rail vibration with respect to the lateral rail location on the bridge. According to this figure, rail vibration is minimized if the rails centerline locates on the centerline of the cable bridge.

Effects of the height and cross section dimensions of the tower on maximum amplitude of deck vibration are investigated in Figure 7. The results show that with decrease in tower cross sectional area, maximum rail displacement increases. Also according to this figure, there is an optimum tower height in which the maximum rail displacement will be minimum.

Figure 7 Effects of tower height on maximum displacement of rail

Effects of number of cables and number of strands in each cable on maximum displacement of rail are shown in Figure 8. The results show that with increase of these parameters the rail displacement decrease and the bridge become more rigid.

Figure 8 Effects of number of cables and number of strands in each cable on maximum displacement of rail
Vertical displacement of the rail and Vertical position of wagon center of mass when the train passes over the bridge are presented in Figures 9 and 10, respectively. According to these figures maximum vibration of wagon position and rail displacement occur when the wagon reaches the middle of the bridge.

![Fig. 10 Vertical position of wagon center of mass](image)

The comfort of the passenger coach in a running train can be assessed using the Sperling factor defined as:

\[
Sperling \text{ factor} = 0.896 \frac{V_{av}^3 \text{(cm/s}^2\text{)}}{f} F(f) \tag{49}
\]

Where \( f \) is the frequency in Hz; and \( F(f) \) is the modification coefficient of frequency. When vertical vibration is concerned,

\[
F(f) = \begin{cases} 
0.325 & 0.5 < f < 5.9 \\
\frac{400}{f^2} & 5.9 < f < 20 \\
1 & f > 20
\end{cases} \tag{50}
\]

The allowable value of vehicle comfort is 3.0 for vertical vibrations [3].

The acceleration response of the car body is random due to random rail irregularities and it contains a wide range of vibration frequencies. Thus, the Sperling comfort index is calculated for a series of frequencies based on the Fourier spectrum of the acceleration response time history. Acceleration response of the car body for different wagon speeds and line grades is presented in Figures 11 and 12.

Using these results Sperling comfort index is calculated and presented in Figure 13. It can be seen that the Sperling index is less than 2, indicating that the ride comfort is satisfactory.
5. Validation of the model

Example 1: To validate the model illustrated in this paper its predictions of the responses are compared with the responses are reported by Xu et al. [3] for the case where there are no cross wind forces. The vertical displacement response of bridge girder at mid-span evaluated by the current model and that of presented Xu et al. [3] are shown in Figures 14(a) and (b) respectively. According to these figures, the difference of the maximum amplitudes of the two results is about 5.5%. Therefore the prediction of the responses by the current model is in good agreement with the responses reported by Xu et al. [3].

Example 2: Yau and Yang [2] reported their results of the finite element simulation on the study of vertical interaction between the high speed trains and the cable bridges. In this research the train has been modeled as a series of sprung masse, the bridge deck and towers by nonlinear beam-column elements, and the stay cables by truss elements with Ernst’s equivalent modulus. Using the finite element procedure, the impact factor $I$ has been
solved for the midpoint of the arrival span and departure span of the cable-stayed bridge. Figures 15 show the comparison of the impact factor \( I \) with respect to the speed parameter \( S \) from the reference and the calculated impact factor using the current model. It can be seen from Figures 15(a) and (b), that the numerical results predicted by the present model are in reasonable agreement with the results calculated by finite element method.

**Fig. 14** Vertical displacement response of bridge girder at mid-span

**Fig. 15** Impact factor of the cable-stayed bridge
Example 3: The model developed by Au et al. [1] has been used for validation of the dynamic model of wagon and bridge interaction as reported in this paper. In that paper, the impact factor of deck moment was obtained using 2D model analyzed by the FEM. Figure 16 shows the comparison of the impact factor calculated using the current model with the results presented by Au et al. [1]. According to this figure the magnitude of the impact factor of the current model has a certain deviation compared with the values obtained by Au et al. [1] and the maximum error is about 5.8%.

![Comparison of the impact factor for 2D and 3D models](image)

6. Conclusion

In this paper a 3-D nonlinear models of cable bridge and wagon have been used to investigate the interaction of the cable bridge and train system. The current model has been validated using several numerical models reported in the literature by other researchers. Using this model; the effects of wagon velocity, lateral position of the rails and rail irregularities on wagon/bridge vibration and passenger comfort have been studied.

List of Symbols

- $A$: Cross section area
- $a$: Geometric slope
- $C$: Fastener damping in vertical direction
- $\alpha$: Poisson's ratio
- $D$: Flexural rigidity
- $\rho$: Density
- $E$: Module of elasticity
- $\omega$: Angular velocity
- $F$: Force
- $(\cdot)^r$: Relative frame
- $H$: Tower height
- $(\cdot)^h$: Horizontal direction
- $I$: Second moment of area
- $(\cdot)^l$: Lateral direction
- $K$: Fastener stiffness in vertical direction
- $(\cdot)^v$: Vertical direction
- $L$: Length or distance between different elements
- $(\cdot)_b$: Bogie
- $N$: Number of
- $(\cdot)_c$: $C^b$th cable
- $(\cdot)_f$: Fastener
- $(\cdot)_k$: $K^b$th rail or tower
- $(\cdot)_h$: Initial frame
- $(\cdot)_r$: Rail
- $(\cdot)_m$: Mass
- $(\cdot)_r$: Right side of tower
- $(\cdot)_v$: Velocity
- $(\cdot)_w$: Rail to bridge deck
- $(\cdot)_d$: Displacement
- $(\cdot)_w$: Rail to wheel
- $(\cdot)_e$: Bridge deck
- $(\cdot)_n$: Tower to bridge deck
- $(\cdot)_a$: Bridge deck to rail
- $(\cdot)_w$: Wheel to rail
- $(\cdot)_s$: Bridge deck to tower
- $(\cdot)_w$: Wagon
- $(\cdot)_t$: Tower
- $(\cdot)_s$: Wheel to rail
- $(\cdot)_l$: Left side of tower
